

The cover image illustrates the relationship between  $\beta_{\text{Heavy}}$ -spectrin (in green) and Coracle (in red) in the tubular *Drosophila* salivary gland epithelium.  $\beta_{\text{H}}$ -spectrin is heavily concentrated at the apical luminal surface, whereas Coracle is limited to the apical-lateral septate junctions at the cell boundaries. This image was made through a maximum projection of a confocal data stack. The boundary between these two domains is degraded in the absence of the  $\beta_{\text{H}}$ -spectrin-binding protein Annexin B9. See Tjota et al. (pp. 2914-2926).
